## 1. Prioritize populations for population restoration

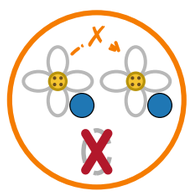

**AVOID**

**over-producing**

*inbreeding depression*

→ excluded as a seed source

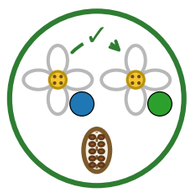

**TARGET**

**mate-limited**

*too few compatible mates*

→ genetic rescue (objective 3)

**INTACT**

**reproductively intact**

*enough compatible mates*

→ seed source (step 2): protect

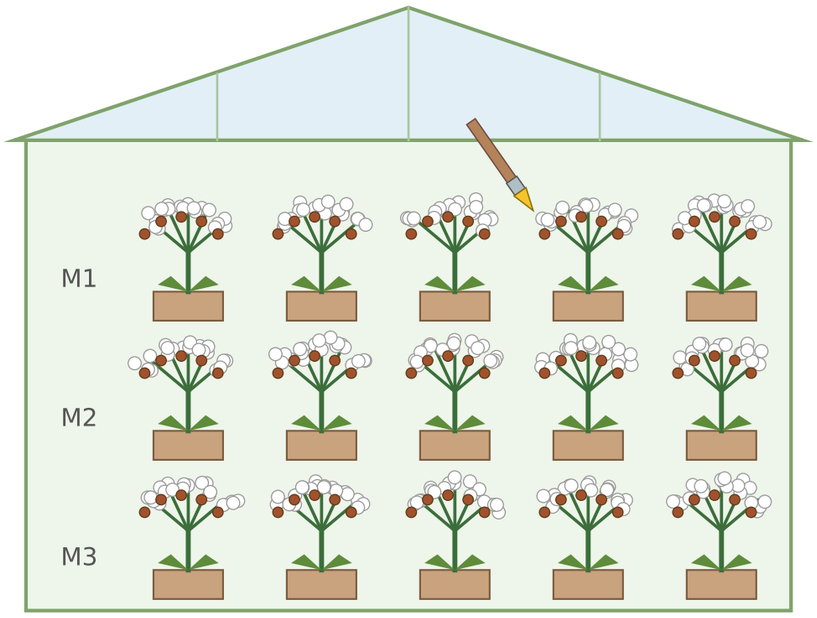

*population = the plants that mate together (the mating pool)*

**technique: seed set for plant size (see Figure 4)**

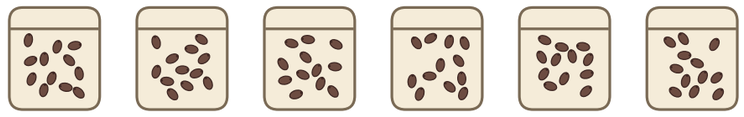

## 2. Multiply seed for intact (source) populations

from sources

**many seeds**

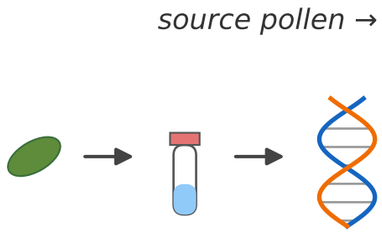

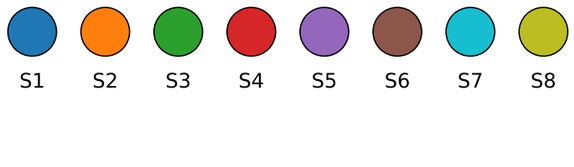

**technique: seed bulking (greenhouse)**

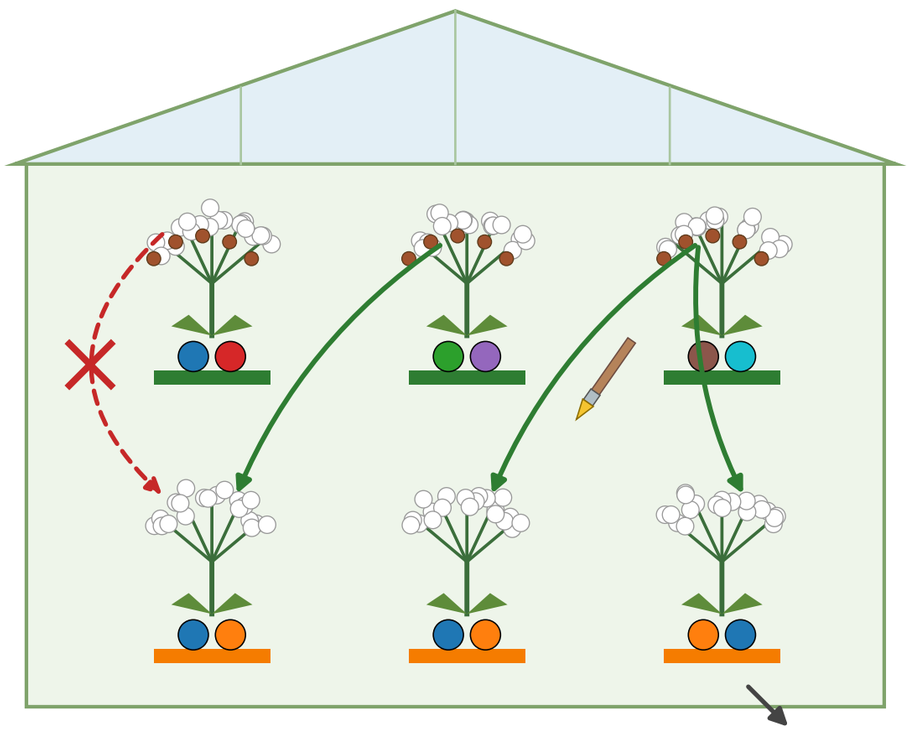

## 3. Rescue target (mate-limited) populations

### 3a. Breed seed with new S-alleles

*source pollen → target flowers, pairs chosen by SRK*

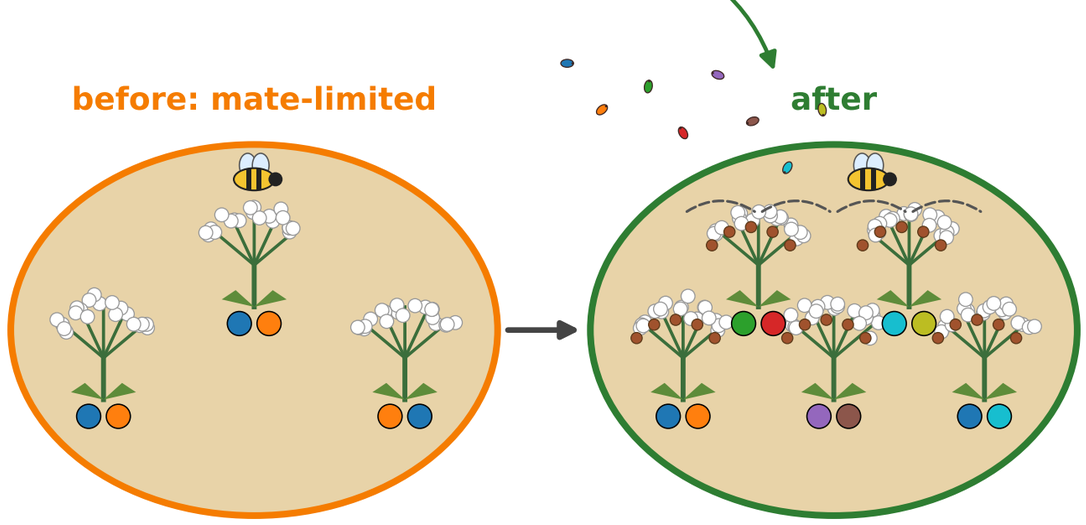

seed with new S-alleles

**technique: informed breeding (SRK)**

### 3b. Sow the seed into the population

monitor

**technique: seed outcasting**
