1. Plant phenotyping

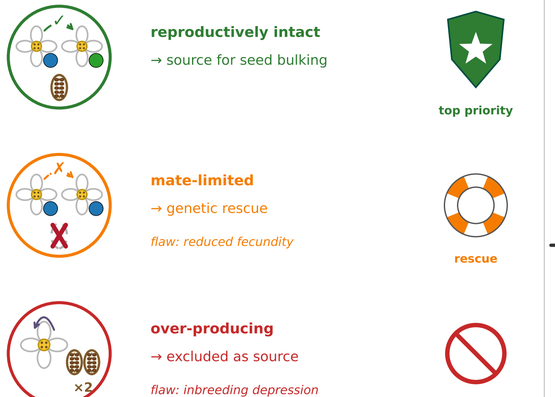

plant size + seed yield, every plant, two seasons

2. Predicting reproductive status

build on all plants → deploy by population

3. Sort populations for restoration

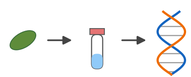

hypotheses → tested with genetics (panel 4)

4. Test with genetics

Why test?

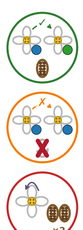

seed yield can also be driven by
resource or pollinator availability

our research: pollinators are not limiting → genetics

SRK gene:
the S-types of every plant

what genetics should show

reproductively intact
many S-types, many compatible mates

mate-limited
few S-types, few compatible mates

over-producing
seeds carry only the mother's S-types (selfing)
