1. Plant phenotyping

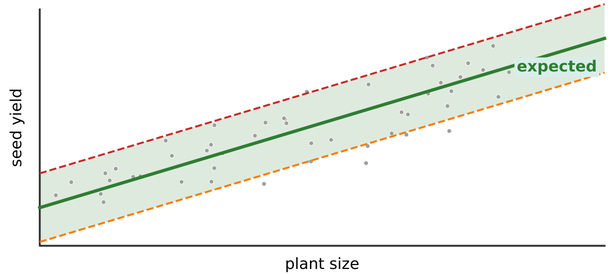

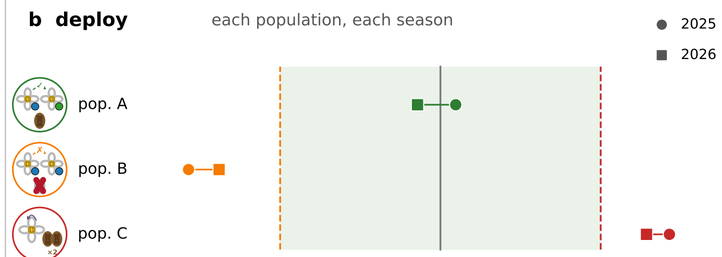

plant size + seed yield, every plant, two seasons

2. Predicting reproductive status

a build all plants → seed yield expected for size

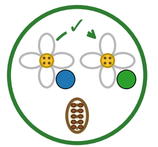

b deploy each population, each season

build on all plants → deploy by population

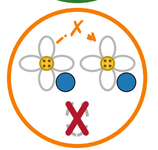

3. Sort populations for restoration

reproductively intact

→ source for seed bulking

top priority

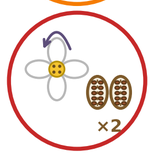

mate-limited

→ genetic rescue

flaw: reduced fecundity

rescue

over-producing

→ excluded as source

flaw: inbreeding depression

avoid

Hypotheses → test with genetics

plant size and seed yield can also be driven

by resource or pollinator availability

our research shows pollinators are not limiting → we focus on genetics

→ test with the SRK gene (S-types):

S-allele diversity, compatible mates, selfing
