1. Survey slick spots holding reproductive plants

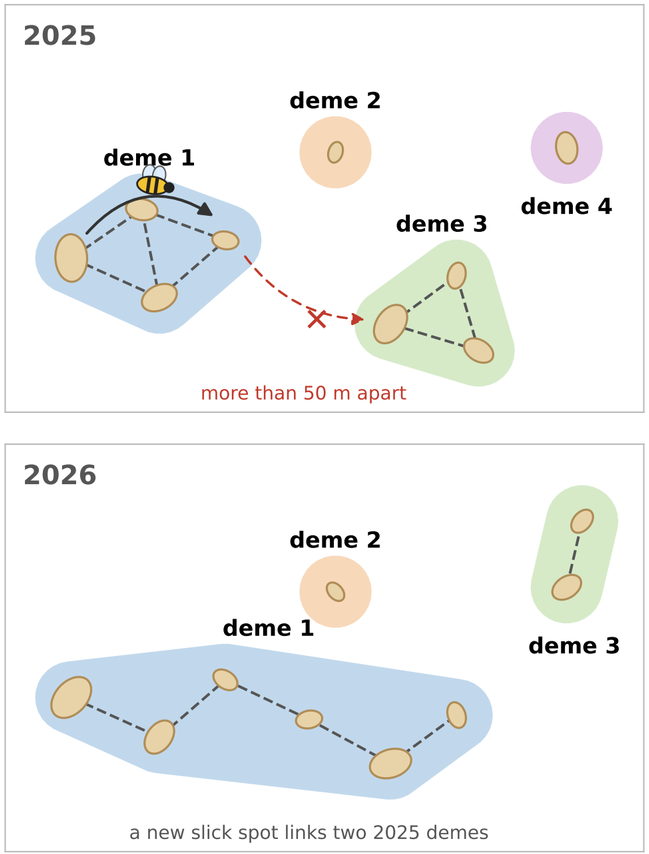

technique: field survey, two seasons

Each slick spot surveyed in a season is an event; its reproductive plants are counted. Some slick spots are not above ground every season.

< 50 m

2. Determine the mating pool (demes)

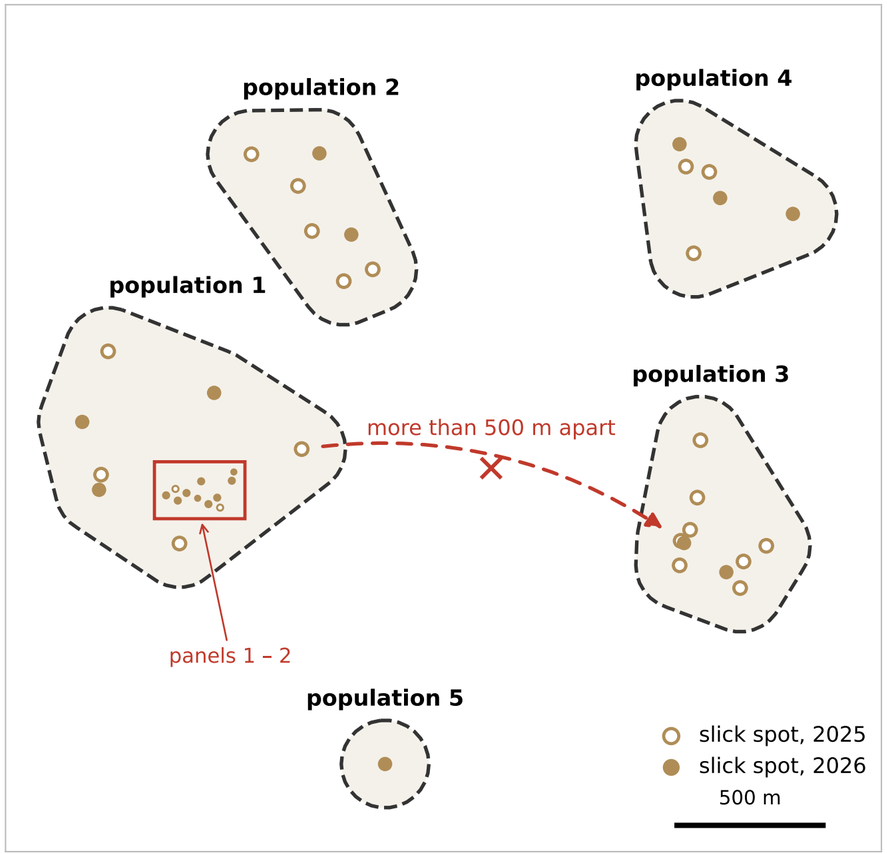

technique: pollinator flight, < 50 m

Plants less than 50 m apart can mate: their slick spots form one deme, the mating pool, redrawn each season.

< 500 m, both seasons

3. Determine populations — the units to prioritize

technique: maximum pollinator dispersal, < 500 m

Slick spots of both seasons within the maximum pollinator dispersal (500 m) form one population — the unit for seed collection, restoration and prioritization.

Schematic — positions are invented, not a real site.
